Abstract: Evaluation of a specimen of Ptilotus R.Br. (Amaranthaceae), collected from a remote location in the northern Kimberley, reveals it to be a unique taxonomic entity. The morphological differences between this entity and its closest relatives P. distans (R.Br.) Poir. and P. capensis (Benl) A.R.Bean are discussed and found to support its recognition as the new species Ptilotus crinitus T.Hammer & R.W.Davis. An identification key is given for the three species.

Keywords: Amaranthaceae, new species, Ptilotus, taxonomy, Western Australia

Introduction

Ptilotus R.Br. (Amaranthaceae) encompasses approximately 125 species with most of the taxonomic diversity within the genus occurring in arid or semi-arid Australia, particularly in Western Australia’s Eremaean province (Hammer et al. 2018, 2019b). Smaller numbers of species are native to monsoonal northern Australia or temperate southern Australia.

Ptilotus distans (R.Br.) Poir. is a species endemic to northern Australia, occurring mainly in the north of the Northern Territory (i.e. the ‘Top End’) and with three records (K.F. Kennedy 11109, PERTH01647946; M.D. Barrett MDB 4917, PERTH09302077; R.L. Barrett 737, PERTH06606806) from the Kimberley, Western Australia. Ptilotus distans is a member of a species group with P. fusiformis (R.Br.) Poir., P. xerophilus T.Hammer & R.W.Davis and P. polyspathys (Gaudich.) F.Muell. (i.e. the P. fusiformis species group). These species together with five others form a well-supported subclade of what has been informally referred to as ‘Clade D’ (Hammer et al. 2019a). Some typical characters within the subclade are an herbaceous habit, greenish flowers (sometimes tinged pink) that are presumably moth-pollinated (e.g. some have nocturnal anthesis, see Hammer et al. 2019a), and with the typically five fertile stamens commonly reduced to four, plus one inconspicuous staminode.

Benl (1984) described P. distans subsp. capensis Benl from the York Peninsula, Queensland. He differentiated this subspecies from typical P. distans (i.e. in the Northern Territory) based on staminal filament and style lengths and differences in the indumentum on the bracts, staminal cup and ovary. Bean (2008) considered the differences between these two subspecies to be significant enough to warrant them to be recognised as distinct species, so he raised Benl’s taxon to species rank as P. capensis (Benl) A.R.Bean.

The present study evaluates the morphology of a specimen that was collected from a remote coastal area in the northern Kimberley, Western Australia and initially identified as Ptilotus aff. distans (referred to below as Ptilotus crinitus).

Methods

This study was based on examination of dried specimens of Ptilotus housed at PERTH and AD.

Results and discussion

Within the genus, the new species Ptilotus crinitus is most similar to P. distans but can be segregated by its habit, bract shape and size, and sepal indumentum.

Ptilotus crinitus is quite different in habit to Ptilotus distans and P. capensis. These species are few-branched, narrow and erect tuberous herbs, 0.3–1 m high (e.g. see specimens, K000356752 and K000356753, available at https://plants.jstor.org/stable/10.5555/al.ap.specimen. k000356752). The new species is a rounded herb or shrub with lateral ascending branches to 40 cm high with numerous branches (Fig. 1). Unfortunately, neither the root system nor the base of the plant was collected, and a measurement as to the width of the whole plant was not recorded.
The bracts of *P. crinitus* are similar to *P. capensis* in being narrowly lanceolate but are much shorter (2.9–3.2 mm) and narrower (0.7–0.9 mm) than those of *P. capensis* (c. 5.2 mm long and c. 1.5 mm wide). The bracts of *Ptilotus distans* differ in shape to the other two species, being ovate, and are much wider than *P. crinitus* at 1.6–2 mm wide. *Ptilotus distans* has a bract length of 2.3–3.8 mm long, similar to *P. crinitus*.

The hairs on the outer surface of the sepals of *P. crinitus* are up to 8 mm long and extend beyond the sepal apex by 1–2 mm (Fig. 2D). Sepal hairs in *P. capensis* and *P. distans* are at most half of the length (to 4 mm long) and do not extend beyond the sepal apex (Fig. 2B). The sepals of *P. crinitus* are more finely tapering than those of *P. distans* (especially the inner three), so much so that the apex is more or less obscured within the hairs that surpass it (Fig. 2A, D).

We find that the differences in these characters are sufficient to recognise the new entity at species rank, and therefore we formally describe it below as *Ptilotus crinitus* T.Hammer & R.W.Davis.

**Taxonomy**

*Ptilotus crinitus* T.Hammer & R.W.Davis, sp. nov.

Rounded and ascending perennial herbs or subshrubs 30–40 cm high, numerous branches. Stems spreading and ascending, angled, ribbed, glabrous or with very sparse hairs. Leaves narrowly lanceolate to narrowly elliptical, 5–20 mm long, 0.4–0.8 mm wide, glabrous; base sessile; margins entire; apex acute. Inflorescences terminal, spiciform, interrupted, 3–10 cm long, <10-flowered, flowers spaced 1–2 cm apart. Bracts narrowly lanceolate, 2.9–3.2 mm long, 0.7–0.9 mm wide, translucent, central portion with a few sparse thickened hairs to c. 0.2 mm long; midrib darkened; apex acute. Bracteoles narrowly ovate, uneven in size, 5.5–7.0 mm long, 2.9–3.1 mm wide, opaque, straw-coloured, glabrous or with a few sparse fine hairs to c. 0.5 mm long; midrib prominent, pinkish; apex acute. Outer sepals narrowly lanceolate, 12.0–13.0 mm long, 1.4–1.5 mm wide at the base; adaxial surface glabrous, tinged pale pink; abaxial surface with sub-verticillate hairs to 8 mm long that exceed the sepal apex by 1.0–2.0 mm; apex very narrowly attenuate. Inner sepals narrowly lanceolate, 11.5–12.0 mm long, 1.4–1.5 mm wide at the base; adaxial surface with a few fine hairs on the margin, tinged pale pink; abaxial surface with sub-verticillate hairs to 8 mm long that exceed the sepal apex by 1.0–2.0 mm; apex very narrowly attenuate. Fertile stamens 3; filaments uneven in length, 2.5–3.0 mm long, with silky hairs c. 0.5 mm long on the dilated base; anthers 0.9–1.0 mm long, 0.2–0.3 mm wide. Staminal tubes 2, 1.3–1.5 mm long. Staminodes 2, 0.4–0.6 mm long, symmetrical, lacking appendages, with long fine silky hairs to c. 1.5 mm long. Ovary ovoid, 1.8–2.0 mm long, 1.3–1.5 mm wide, with silky hairs to c. 0.8 mm long on the apical ½ of the ovary surface; style very short and flattened, 0.1–0.2 mm long. Style slightly to distinctly curved, 2.0–2.5 mm long, slightly excentric on the ovary apex. Stigma unlobed, distinctly capitrate. Seeds not seen.

**Diagnostic features.** *Ptilotus crinitus* can be distinguished from all other members of the genus by the combination of being a perennial herb or subshrub to c. 40 cm high and having narrowly lanceolate to narrowly elliptical glabrous leaves <0.9 mm wide, interrupted inflorescences with flowers spaced flowers 1–2 cm apart, narrowly lanceolate bracts 2.9–3.2 mm long and 0.7–0.9 mm wide, hairs on the abaxial surface of the sepals to 8 mm long and exceeding the sepal apex by 1–2 mm, a staminal cup with long silky hairs, and an ovary with long silky hairs (to c. 0.8 mm long) on the distal half.

**Phenology.** Flowers recorded for February, probably January to April.

**Distribution and habitat.** *Ptilotus crinitus* is only known from one record in northern Kimberley, where it was collected near the beach on shallow sand over sandstone and in a low open eucalypt woodland over tussock grassland.

**Conservation status.** *Ptilotus crinitus* is currently only known from a single location in the remote northern Kimberley, Western Australia. We therefore recommend that this taxon be listed as Priority One under the Conservation Codes of Western Australian Flora (Smith & Jones 2021).

**Proposed vernacular name.** Long-haired mulla mulla.
**Etymology.** The specific epithet is from Latin for “long-haired”, which refers to the hairs on the abaxial surface of the sepals that exceed the sepal apex.

**Taxonomic Notes.** Flowers on *P. crinitus* were found to have three fertile stamens and two staminodes. Four fertile stamens and one staminode are typical for all other species in the *P. fusiformis* species group, including for *P. distans* and *P. capensis*. Benl (1984), reported *P. distans* subsp. *capensis* to have typically four fertile stamens, but found it to rarely have five or three. Fertile stamen number is usually consistent within *Ptilotus* species, except with a few notable cases (e.g. *P. manglesii* (Lindl.) F.Muell.; see Hammer 2020). It may be that

Fig. 2. Composite image comparing the indumentum between *P. distans* (A–C) and *P. crinitus* (D–F): whole flower (A, D), outer sepal (B, E) and ovary (C, F). — A–C K.F. Keneally 11109 (PERTH01647946), D–F G.J. Keighery & M.N. Lyons KIBS 1188 (PERTH09170898). Note: Separate scales were used for the flowers and sepals (A, B, D, E; scale bar = 2 mm) versus the ovaries (C, F; scale bar = 1 mm).

having three fertile stamens is typical for *P. crinitus* or it could vary in number like in *P. capensis*.

Benl (1984) described the ovary indumentum of *P. distans* subsp. *distans* as being shortly pubescent in the upper half with simple hairs, 0.2–0.3 mm long, and the ovary indumentum of *P. capensis* consisting of articulate hairs to 2.4 mm long. This is in contrast to Bean (2008), who described the hairs on the ovary of *P. distans* to be pubescent, non-articulate and to 1.4 mm long and the ovary hairs of *P. capensis* to 3.3 mm long. Our examinations of *P. distans* specimens at PERTH and AD only found ovary hairs of the type described by Benl (i.e. pubescent and 0.2–0.3 mm long). We found that *P. crinitus* had silky and articulate hairs on the ovary to c. 0.8 mm long, which are noticeably longer and of a different texture than those typical of *P. distans* (Fig. 2C, F). Since we could not confirm the indumentum characters described by Bean (2008), we believe that ovary indumentum may be an additional difference between *P. crinitus* and *P. distans*, at least for most morphotypes of *P. distans*.
